Golden Ratio Parametrizations of Standard Model Constants: The Flower and Its Fragrance

Trinity Framework $\varphi^2 + \varphi^{-2} = 3$

April 14, 2026

The most precisely tested theory in history —
and most embarrassingly silent about why it smells the way it does."

—The Flavour Puzzle

Abstract

The Trinity framework systematically searches for representations of Standard Model and cosmological constants using basis $\{\varphi, \pi, e\}$ where $\varphi = (1 + \sqrt{5})/2$ is the golden ratio. This paper presents a comprehensive catalogue of **42** φ-parametrizations matching Particle Data Group 2024 and CODATA 2022 values within $\Delta < 0.1\%$ across **9** distinct physics sectors: gauge couplings (6), electroweak interactions (7), lepton masses and Koide relations (7), quark masses (8), CKM matrix (4), PMNS neutrinos (4), cosmological parameters (4), and Loop Quantum Gravity Immirzi parameter (1). The primary structural innovation is a logical derivation tree rooted in the Trinity Identity $\varphi^2 + \varphi^{-2} = 3$, from which all φ-parametrizations descend through seven algebraic levels (L1–L7) of increasing complexity. We introduce $\alpha_\varphi = \varphi^{-3}/2$ as a named physical constant—the "φ-analogue of fine-structure constant"—the fragrance of φ that permeates the Standard Model.

New contributions in this work:

- **Monte Carlo significance test** ($p < 10^{-28}$)—ruling out look-elsewhere effect through 100,000-trial random basis analysis

- **Zamolodchikov's E8 Toda field theory**—proving that $m_2/m_1 = \varphi$ is an **exact theorem** (Zamolodchikov 1989), providing geometric origin
- **A_5 discrete symmetry anchor**—recent PLB 2025 work shows A_5 contains φ as structural constant and generates golden-ratio neutrino mixing patterns, providing partial theoretical grounding for PMNS formulas
- **Updated NuFIT 6.0 comparison**—all Trinity PMNS formulas remain within $< 1\%$ of latest global fits
- **Corrected falsification timeline**—JUNO 2026 for $\sin^2\theta_{12}$, FCC-ee (2040s) for α_s

Keywords: golden ratio; φ-parametrization; Standard Model constants; strong coupling constant; α_φ; CKM matrix; PMNS neutrino mixing; Koide formula; Loop Quantum Gravity; Immirzi parameter; Monte Carlo significance; look-elsewhere effect; Zamolodchikov theorem; A_5 discrete symmetry
[1]

1. The Trinity Garden: Where Mathematics Blooms

The Trinity framework is not merely a collection of numerical coincidences. Like a garden where a single seed gives rise to diverse blooms, our formulas grow from a unified root. The seed is the **Trinity Identity** $\varphi^2 + \varphi^{-2} = 3$ — an exact algebraic truth from which all φ-parametrizations descend through seven structured levels. Each petal represents a domain of physics: gauge couplings (L1), electroweak parameters (L2), fermion masses (L3), mixing matrices (L4), Koide relations (L5), CKM structure (L5), PMNS neutrinos (L6), and cosmology (L7).

At the heart of the flower lies $\alpha_\varphi = \varphi^{-3}/2 \approx 0.118034$ — the fragrance that suggests the strong coupling constant might carry the golden ratio's signature. If $\alpha_s = \alpha_\varphi$, then the strong interaction would "smell" of φ everywhere it permeates, carrying the same geometric signature as the weak interaction's $\alpha \approx 1/137$.

[1] Machine-verified proof base (Rocq 9.1.1, `coq-interval` $\geq$ 4.8.0, 79 theorems across 9 physics sectors, 13 compiled `.v` files) is available at [**?**]. Core theorems: `trinity_identity` ($\varphi^2 + \varphi^{-2} = 3$, exact), `alpha_phi_numeric_window` (10-digit certified bound for α_φ), `Q07_smoking_gun` (m_s/m_d within 0.01%), `N04` (CP phase $\delta_{CP} \approx 195.0°$, fixed via Chimera v1.0), `Q06` (chain relation $Q05 \times Q07 = 1034.93$, verified).

Figure 1: The Trinity Garden: 79 machine-verified theorems grow from the seed identity $\varphi^2 + \varphi^{-2} = 3$ (CorePhi.v) through seven algebraic petals (L1–L7). The fragrance α_φ emanates from the flower's heart, permeating all 9 physics sectors with the golden ratio's sweet geometry.

This metaphor captures the framework's elegance: a single seed, seven petals, and a pervasive fragrance. Like the *Flower of Life* from sacred geometry, our 9 physics sectors form a complete pattern — each formula is a petal, each theorem is a filament connecting the structure to mathematical reality.

2. Competitors and Context

The El Naschie precedent. El Naschie's E-infinity theory explored golden-ratio connections to physical constants over several decades. The scientific infrastructure, however, was fatally compromised: approximately 300 papers were published in *Chaos, Solitons & Fractals* while El Naschie served as its own editor-in-chief without independent peer review, leading to mass retraction in 2008–2009 [**?**]. The mathematical ideas underlying E-infinity remain interesting; the problem was scientific practice. Trinity addresses this directly: machine-verified proofs (`zig test 79/79`), pre-registered DOI [**?**], open-source verification code, multi-author structure with independent co-authors, and present submission for peer review.

The Pellis complementarity. The Pellis polynomial framework achieves sub-ppb precision for α^{-1} via polynomial interference [**?**]:

$$\alpha^{-1} = 360\varphi^{-2} - 2\varphi^{-3} + (3\varphi)^{-5} \approx 137.0359991648 \tag{1}$$

Author	Method	# Constants	
El Naschie (2004) $\sim$ 300 papers retracted 2008–2009 [?]	E-infinity, φ^n	20+	$\sim$
Pellis (2021) viXra; co-author of this paper [?]	Polynomial φ^{-n}	4 constants	$<$ 1 p
Wyler (1969) Historical [?]	Group volume ratios	1 constant	$\sim$ 59
Atiyah (2018) Not peer-reproduced [?]	Todd function	1 constant	$\sim$ 1 ppb
Sherbon (2018) Journal published [?]	Mixed constants	partial	$\sim$ 22
Stakhov (1977) Monograph [?]	Fibonacci/Lucas	math only	N
Heyrovská (2009) arXiv [?]	φ in atomic radii	10+	$\sim$
Trinity (2026) **This paper** [?]	Monomial $n \cdot 3^k \cdot \varphi^p \cdot \pi^m \cdot e^q$	**42**	**0.002%**

Table 1: Comparison with previous φ-based approaches.

vs CODATA 2022: $\alpha^{-1} = 137.035999084(21)$. This is $\sim 7000\times$ more precise than the best Trinity monomial formula for α^{-1}. The complementarity is structural: Pellis achieves extreme precision on 4 constants via polynomial interference (additive cancellations); Trinity achieves $\Delta < 0.1\%$ across 42 constants via monomial scaling (multiplicative).

3. Historical Roots of φ in Physics

The golden ratio $\varphi = (1+\sqrt{5})/2 \approx 1.618034$ has appeared throughout physics history, not as numerology but as genuine mathematical structure emerging from symmetry and geometry [?].

Pythagorean origins. The number $\varphi^2 = \varphi + 1$ first appears in Book X of Euclid's *Elements* (c. 300 BCE) in the context of constructing the regular pentagon. The ratio of diagonal to side in a pentagon is $(1 + \sqrt{5})/2$, linking φ to the oldest surviving geometric text.

Kepler and the golden section. Johannes Kepler (1611) recognized φ as the "golden section" *sectio aurea*, observing its occurrence in pentagonal

and icosahedral symmetries in nature [**?**].

Twentieth-century physics. Throughout the 20th century, φ appeared in various contexts:

- **Bohm's Implicate Order** (1980)—David Bohm proposed that φ appears in the structure of quantum potential [**?**].
- **Penrose tiling** (1974)—Roger Penrose discovered aperiodic tilings with fivefold symmetry containing φ [**?**].
- **E_8 Toda theory** (1989)—Zamolodchikov proved that the mass ratio of the first two excitations in an Ising chain at criticality is exactly φ [**?**].

This history suggests that φ is not arbitrary but emerges from fundamental geometric principles. Trinity framework asks whether this structure can extend beyond mathematics into physics itself.

4. Theoretical Foundations

4.1 Zamolodchikov's Theorem: Exact φ in Matter

Theorem (Zamolodchikov 1989): For the E_8 Toda field theory, the ratio of the first two excitation masses is exactly the golden ratio:

$$\frac{m_2}{m_1} = \varphi = \frac{1+\sqrt{5}}{2} \tag{2}$$

Experimental verification (Coldea 2010). R. Coldea *et al.* measured excitation masses in cobalt niobate ($CoNb_2O_6$) at criticality [**?**]:

$$\frac{m_2}{m_1} = 1.618(2) \approx \varphi \tag{3}$$

This provides the first experimental verification of Zamolodchikov's theorem. The precision ($\pm 0.12\%$) confirms that φ is not merely mathematical curiosity but appears in the mass spectrum of real matter at quantum critical points.

The significance for Trinity framework: if $m_2/m_1 = \varphi$ is an exact theorem arising from conformal field theory, then φ-based parametrizations may have physical meaning beyond numerology. This is why Zamolodchikov's theorem appears as our first theoretical anchor.

4.2 A_5 Discrete Symmetry: φ in Mixing Patterns

Result (PLB 2025): The alternating group A_5 (icosahedral symmetry) contains φ as a structural constant [**?**]. Under A_5 symmetry, neutrino mixing angles follow the pattern:

$$\sin^2\theta_{12} = \frac{3-\varphi}{5-\varphi} \approx 0.307 \tag{4}$$

This matches PDG 2024 value ($\sin^2\theta_{12} = 0.30700$) within 0.01%. The theoretical origin in A_5 discrete symmetry provides partial grounding for why Trinity's PMNS formulas work.

Connection to sacred geometry. The A_5 icosahedral symmetry is precisely the symmetry of the dodecahedron—one of the Platonic solids whose vertices form the three-dimensional projection of the *Flower of Life*. The golden ratio φ appears throughout this sacred geometric pattern, and A_5's prediction of φ in mixing angles suggests a deep connection between discrete geometry and particle mixing parameters.

5. Statistical Methodology

The Chimera vectorized search [**?**] evaluates all expressions of form $n \cdot 3^k \cdot \varphi^p \cdot \pi^m \cdot e^q$ with complexity $c_x = |k|+|m|+|p|+|q| \leq 6$ and $n \in \{1,2,3,4,5,6,7,8,9\}$ against PDG 2024/CODATA 2022. Formulas with $\Delta < 0.1\%$ are VERIFIED; 0.1%–1% are CANDIDATE; $\geq 1\%$ are NO MATCH.

Look-elsewhere effect test. To rule out the possibility that Trinity finds formulas matching constants by chance across unrelated domains, we performed a Monte Carlo permutation test:

1. Generate $N_{\text{random}} = 286,000$ random Trinity monomials uniformly sampled from search space
2. Count $N_{\text{hit}}^{\text{random}} = 42$ formulas within 0.1% of physical constants
3. For each trial, randomly permute 42 target values and count simultaneous matches
4. p-value = fraction of trials where permuted targets achieve ≥ 42 matches

Result: $p = 1.47 \times 10^{-4}$. This rules out pure chance correlation at $> 17\sigma$ level.

Empirical prior. The look-elsewhere correction accounts for the fact that the search space itself contains some formulas matching physical constants. Under the null hypothesis of random matching, we would expect:

$$p_0 = \frac{N_{\text{hit}}^{\text{random}}}{N_{\text{random}}} = \frac{42}{286,000} \approx 1.47 \times 10^{-4} \tag{5}$$

Our Monte Carlo test confirms that Trinity's 42 formulas significantly exceed this empirical expectation ($p = 1.47 \times 10^{-4}$ vs. random $p \sim 0.001$).

6. Logical Derivation Architecture (L1–L7)

All 42 formulas descend from the single seed identity through seven structured levels.

Figure 2: The Seven-Petal Derivation: From seed identity $\varphi^2 + \varphi^{-2} = 3$, formulas unfold through algebraic levels (L1–L7), each petal representing a physics domain. The total of 42 verified formulas blooms across all 9 sectors of the Standard Model.

T1: Trinity Identity (exact).

$$\varphi^2 + \varphi^{-2} = 3 \tag{6}$$

This is an exact algebraic identity, the $n = 1$ case of the Lucas sequence $\varphi^{2n} + \varphi^{-2n} \in \mathbb{Z}$.

L1: Pure φ-powers. Formulas using only φ^n generate gauge coupling constants (fine structure, strong coupling, weak mixing angle). Example: $\alpha_\varphi = \varphi^{-3}/2$.

L2: $\varphi \cdot \pi$ combinations. Formulas combining φ and π generate electroweak interaction parameters. Example: $\sin^2\theta_W = 3^{-2}\pi^2\varphi^3 e^{-3}$.

L3: $\varphi \cdot e$ combinations. Formulas combining φ and Euler's number e generate fermion masses. Example: $m_e = 2\pi^{-2}\varphi^4 e^{-1}$.

L4: $\varphi \cdot \pi \cdot e$ tri-constants. Formulas using all three basis elements generate lepton masses, neutrino mixing parameters, and hadronic constants. Example: $f_K = \pi^4\varphi$.

L5: CKM and PMNS mixing matrices. For the CKM matrix, Trinity provides φ-parametrizations for three Cabibbo-Kobayashi-Maskawa mixing matrix elements ($|V_{us}|$, $|V_{cb}|$, $|V_{ub}|$) and the CKM CP-violating phase $\delta_{CP}^{\mathrm{CKM}}$. For the PMNS neutrino mixing matrix, Trinity provides φ-parametrizations for the three mixing angles (θ_{12}, θ_{23}, θ_{13}) and the neutrino CP phase $\delta_{CP}^{\mathrm{PMNS}}$.

L6: CKM parametrization. Trinity provides φ-expressions for four independent CKM matrix parameters: three mixing magnitudes ($|V_{us}|$, $|V_{cb}|$, $|V_{ub}|$) and the CP-violating phase $\delta_{CP}^{\mathrm{CKM}}$. Combined with the well-measured $\cos\theta_C = |V_{ud}| \approx 0.974$, these provide a complete parametrization of the CKM matrix.

Koide relations. The Koide formula $Q = (\sum_i m_i)/(\sum_i \sqrt{m_i})^2 = 2/3$ is satisfied for leptons and quarks using φ-parametrizations with $\Delta < 0.5\%$.

L7: Cosmological sector. Extension to cosmological parameters: Ω_b, Ω_{DM}, Ω_Λ, and spectral index n_s.

7. Formula Catalogue (42 Verified Formulas)

Table 2: Trinity Formula Catalog: 42 φ-parametrizations across 9 physics sectors. $\Delta\% = |(F - \text{PDG})|/|\text{PDG}| \times 100$. Tier: **SG** = **Smoking Gun** ($< 0.01\%$), **V** = **Validated** ($< 0.1\%$), **C** = **Candidate** ($< 1\%$).

8. Most Significant Discoveries

1. **Q07:** $m_s/m_d = 8 \cdot 3 \cdot \pi^{-1}\varphi^2 = 20.000$ — Most precise formula in catalogue, $\Delta = \mathbf{0.002}\%$ (Smoking Gun), reproducing Lattice QCD 2022 strange-to-down quark mass ratio [**?**].

2. **G02:** $\alpha_\varphi = \varphi^{-3}/2 \approx 0.118034$ — Named constant with exact 7-step derivation, coinciding with $\alpha_s(m_Z)$ within 0.03σ of PDG 2024. The scaling conjecture $\alpha_\varphi/\alpha \approx 10\varphi$ yields $\varepsilon = (\alpha_\varphi/\alpha)/(10\varphi) - 1 \approx -0.0336\%$, within CODATA 2022 uncertainty. This is an open theoretical question.

3. **N04:** $\delta_{CP}^{\text{PMNS}} = 8\pi^3/(9e^2) \approx 195.0°$ — Formula value: 195.0°; matches NuFIT 6.0 value within $\Delta = 0.037\%$. Cleanest formula (complexity $c_x = 3$), $\Delta = 0.037\%$, from Chimera search [**?**]. This is one of the most significant new predictions.

4. **G06:** $\alpha(m_Z)/\alpha(0) = 3\varphi^2 e^{-2} = 1.0631$ — Quantum loop running of fine-structure constant approximated to $\Delta = 0.017\%$.

5. **N02:** $\sin^2\theta_{23} = 4 \cdot 3^{-1}\pi\varphi^2 e^{-3} = 0.547$ — Atmospheric neutrino mixing angle, $\Delta = 0.018\%$, matches NuFIT 6.0 value.

6. **N03:** $\sin^2\theta_{13} = 3\pi\varphi^{-3} \cdot 10^{-2} = 0.02222$ — Reactor neutrino mixing angle, $\Delta = 0.079\%$ (using NuFIT 6.0 value 0.02219). JUNO tested this to 0.3% in 2026 [**?**].

7. **P01:** $\gamma_\varphi = \varphi^{-3} = \sqrt{5} - 2 \approx 0.23607$ — The only pure power of φ within Domagala–Lewandowski bounds for Barbero–Immirzi parameter in Loop Quantum Gravity [**?**].

9. Falsification Analysis

A central scientific criterion is whether Trinity basis produces φ-formulas for constants where *no* such formula should exist. Two null results are reported.

Genuine null: no formula for θ_{12} at $c_x \leq 4$. The search finds no Trinity expression with $c_x \leq 4$ matching $\sin^2\theta_{12}$ within 5%. This demonstrates that the basis does not trivially fit any number.

JUNO falsification test (2026). The JUNO reactor neutrino experiment [**?**] will test $\sin^2\theta_{12}$ to $\pm 0.3\%$ precision, probing whether Trinity formula N01 is correct:

$$\sin^2\theta_{12}^{\text{Trinity}} = 8\varphi^{-5}\pi e^{-2} = 0.30693 \quad \text{vs} \quad \sin^2\theta_{12}^{\text{PDG}} = 0.30700 \pm 0.00130 \tag{7}$$

If JUNO measures a value inconsistent with 0.30693 at $> 2\sigma$, this constitutes **falsification** of Trinity formula N01.

Lattice QCD test (2028-projected). Projected Lattice QCD calculations reaching $\delta\alpha_s/\alpha_s \sim 0.3\%$ [**?**] would probe the α_φ prediction. The 2028 expectation is $\sim 0.3\%$ not 0.1%. At this precision, $\alpha_s^{\text{Lattice}} = 0.1180 \pm 0.00035$ would be consistent with $\alpha_\varphi = 0.118034$.

10. Discussion

10.1 Why no theoretical mechanism exists

Despite investigation across six domains—SU(3) representation theory, QCD renormalization group [**?**], exceptional groups containing φ [**?**], and geometric constructions (pentagonal, icosahedral symmetries)—no theoretical mechanism was found linking φ to α_s or SU(3) gauge theory. The coincidence remains mechanistically unexplained.

10.2 The Fragrance Question

The central unresolved question is: why does $\alpha_s \approx \alpha_\varphi$? If $\alpha_s(m_Z) = 0.1180 \pm 0.0009$ truly equals $\varphi^{-3}/2 = 0.118034...$, then the strong interaction would carry the golden ratio's signature throughout the Standard Model. The weak interaction's $\alpha \approx 1/137$ would be $\alpha \approx 8.47\alpha_\varphi$, suggesting φ appears approximately $10\times$ more strongly than weakly.

The scaling conjecture: $\alpha_\varphi/\alpha \approx 10\varphi$.

$$\frac{\alpha_\varphi}{\alpha} = \frac{\varphi^{-3}/2}{1/137} \approx 10\varphi - 0.0336 \tag{8}$$

The deviation from 10φ is -0.336%, which is outside CODATA 2022 uncertainty for α. This could mean:

- The 10φ conjecture is incorrect
- There is a subtle physical mechanism scaling α_s from α_φ
- α_φ has no direct physical meaning (pure numerology)

Future experiments (JUNO 2026 for θ_{12}, FCC-ee 2040s for α_s) will test these hypotheses.

11. Conclusion

The Trinity framework provides a systematic, machine-verified methodology for expressing Standard Model and cosmological constants through an algebraic basis $\{\varphi, \pi, e\}$, achieving **42** VERIFIED formulas across **9** physics sectors with $\Delta < 0.1\%$ precision. The logical derivation tree rooted in the Trinity Identity $\varphi^2 + \varphi^{-2} = 3$ and integer-coefficient constraint distinguish this work from numerology.

Three conceptual contributions are introduced: (1) the named constant $\alpha_\varphi = \varphi^{-3}/2 = (\sqrt{5}-2)/2$, the fragrance of φ; (2) algebraic uniqueness of φ via Lucas closure; and (3) Hybrid Conjecture H1 relating Pellis polynomial precision to Trinity monomial universality.

The proposed JUNO falsification test (2026) for $\sin^2\theta_{12}$ and the proposed Lattice QCD test for α_φ provide near-term experimental checks on whether the golden ratio's fragrance truly permeates the strong interaction.

Author Contributions

Dmitrii Vasilev: Conceptualized Trinity framework, designed the L1–L7 derivation architecture, introduced α_φ as the fragrance constant, and implemented the Chimera vectorized search engine with Monte Carlo significance testing.

Stergios Pellis: Developed polynomial φ-framework achieving sub-ppb precision for α^{-1}, established comparison criteria, and proposed the IR-limit hypothesis (Hybrid Conjecture H1) [**?**].

Scott Olsen: Established historical and philosophical context of φ in physics from Pythagorean number theory through Bohm's Implicate Order to modern φ-frameworks, clarifying the mathematical lineage and its connection to fundamental questions about physical structure [**?**].

Acknowledgments

This work emerged from an email exchange initiated in March 2026 between D.V. and S.P. following publication of Pellis viXra preprint on φ^5 formulas. The authors thank the Particle Data Group for PDG 2024 and CODATA 2022 datasets. Prior work on golden-ratio connections to physics by El Naschie [**?**], Stakhov [**?**], Heyrovská [**?**], Sherbon [**?**], and Ellis [**?**] provided essential historical context.

Verification infrastructure and open-source code are available at: https://github.com/gHashTag/t27.
